ABSTRACT

By using potential effective interaction in the anharmonic correlated Einstein model in XAFS (X-ray absorption fine structure) theory on the basis of quantum statistical theory with phonon interaction procedure, the expressions describe asymmetric component through by the cumulants and thermodynamic parameters including the anharmonic effects contributions and by new structural parameters of cubic crystals have been formulated. This new parameters describe distribution of atoms. The expansion of cumulants and thermodynamic parameters through new structural parameters have been performed.

Keywords: Anharmonic, XAFS, cumulants, thermodynamic, parameters.

INTRODUCTION

In the harmonic approximation X-ray Absorption Fine Structure spectra (XAFS), the theoretical calculations are generally well appropriate with the experimental results at low temperatures, because the anharmonic contributions from atomic thermal vibrations can be neglected. However, at the different high temperatures, the XAFS spectra provide apparently different structural information due to the anharmonic effects and these effects need to be evaluated. Furthermore, the XAFS spectra at low temperatures may not provide a correct picture of crystal structure, therefore, this study of the XAFS spectra including the anharmonic effects at high temperatures is to be needed. The expression of anharmonic XAFS spectra often is described by [4]:

$$
\chi(k) = F(k) \frac{\exp[-2R/\lambda(k)]}{kR^2} \text{Im}\left\{ e^{i\Phi(k)} \exp\left[ 2ikR + \sum_{n} \frac{(2ik)^n}{n!} \sigma^{(n)} \right]\right\},
$$

where $F(k)$ is the real specific atomic backscattering amplitude, $\Phi(k)$ is total phase shift of photoelectron, $k$ is wave number, $\lambda$ is mean free path of the photoelectron, and $\sigma^{(n)}$ ($n = 1, 2, 3,...$) are the cumulants to describe asymmetric components, they all appear due to the thermal average of the function $e^{-2ikr}$, in which the asymmetric terms are expanded in a Taylor series around value $R = \langle r \rangle$ with $r$ is instantaneous bond length between absorbing and backscattering atoms at $T$ temperature and then are rewritten in terms of cumulants.

At first, the cumulant expansion approach has been used mainly fitting the XAFS spectra to extract physical parameters from experimental values. Thereafter, some procedure were formulated for the purpose of analytic calculation of cumulants, and the anharmonic correlated Einstein model [7] which has been given results good agreement with experimental values. The important development in this procedure is that model has been calculated into

1 Email: hieutruongdhttt@gmail.com; quangthogv@gmail.com
the interaction between absorbing and backscattering atoms with neighboring atoms in a cluster of nearest atoms at high temperatures. The potential interaction between the atoms becomes asymmetric due to the anharmonic effects and the asymmetric components were written in terms of the cumulants. The first cumulant or net thermal expansion, the second cumulant or Debye-Waller factor, the third cumulant is description phase shift of anharmonic XAFS spectra. The purpose of this work is to formulate the cumulant expressions and write thermodynamic parameters as general form through the new structure parameters by using the anharmonic correlated Einstein model.

Fomalism

Because the oscillations of a pair single bond between of absorbing and backscattering atoms with masses $M_1$, $M_2$, respectively, is affected by neighboring atoms, when taking into account these effects via an anharmonic correlated Einstein model, effective Einstein potential is formed as follow:

$$U_E(x) = U(x) + \sum_{i=1,2} \sum_{j \neq i} U \left( \frac{\mu}{M_1} \times \hat{R}_{ij} \right)$$  \hspace{1cm} (2)

where $\hat{R}$ is the unit bond length vector, $\mu$ is reduced mass of atomic mass $M_1$ and $M_2$, the sum according to $i, j$ is the contribution of cluster nearest atoms, $U(x)$ an effective potential:

$$U(x) \approx \frac{1}{2} k_{ef} x^2 + k_3 x^3 + \ldots, \hspace{1cm} x = r - r_0$$  \hspace{1cm} (3)

where $r$ is spontaneous bond length between absorbing and backscattering atoms $r_0$ is its equilibrium value, $k_{ef}$ is effective spring constant because it includes total contribution of neighboring atoms, $k_3$ is cubic anharmonicity parameter which gives an asymmetry in the pair distribution function. The atomic vibration is calculated based on quantum statistical procedure with approximate quasi-hamonic vibration, in which the Hamiltonian of the system is written as harmonic term with respect to the equilibrium at a given temperature plus an anharmonic perturbation, with $y = x - a$, $a(T) = \langle x \rangle$, $\langle y \rangle = 0$, we have:

$$H = \frac{P^2}{2\mu} + U_E(x) = H_0 + U_E(a) + \delta U_E(y)$$  \hspace{1cm} (4)

with $a$ is the net thermal expansion, $y$ is the deviation from the equilibrium value of $x$ at temperature $T$. Next, the use of potential interaction between each pair of atoms in the single bond can be expressed by anharmonic Morse potential for cubic crystals. Expanding to third order around its minimum, we have:

$$U_E(x) = D(e^{-2\alpha x} - 2e^{-\alpha x}) \approx D(-1 + \alpha^2 x^2 - \alpha^3 x^3 + \ldots)$$  \hspace{1cm} (5)

where $\alpha$ is expansion thermal parameter, $D$ is the dissociation energy by $U(r_0) = -D$. From expressions (4), (5) we have potential effective interaction Einstein generalize as:

$$U_E(\chi) = U_E(a) + \frac{1}{2} k_{ef} y^2 + \delta U_E(y), \hspace{1cm} x = y + a$$  \hspace{1cm} (6)

Substituting Eq. (5) into (3) and using Eq. (6) to calculate the second term in Eq. (3) with $\mu = M/2$ ($M_1 = M_2 = M$), sum of $i$ is over absorber ($i=1$) and backscatterer ($i=2$), and the sum of $j$ which is over all their near neighbors, excluding the absorber and backscatterer themselves, because they contribute in the $U(x)$, and calculation of ($\hat{R}_{12}, \hat{R}_{ij}$) with lattice
cubic crystals like s.c, fcc and bcc crystals, we obtain thermodynamic parameters like $k_{ef}$, $k_3$ and $\delta U_E(y)$ in Table 1.

**Table 1. The expressions of thermodynamic parameters for cubic crystals**

<table>

The $k_3$ parameter is identical with any structures, the expressions of $k_{ef}$, $\delta U_E(y)$ thermodynamic parameters for the structural cubic crystals generalize according to new structural parameters are the following forms:

$$k_{ef} = c_1(\Delta x^2 + c_2 ak) = \mu_0^2 \chi; \quad \delta U_E(y) = Da^2[c_i\alpha y - 5\alpha y^3/4] \quad (7)$$

To derive the analytical formulas for cumulants through new structural parameters for the crystals of cubic structure, we use perturbation theory [5], [9]. The atomic vibration is quantized as phonon and anharmonicity is the result of phonon interaction. Accordingly, we express $y$ in terms of annihilation and creation operators $\hat{a}^+$, $\hat{a}$, respectively:

$$y = \sigma^0(\hat{a} + \hat{a}^+); \quad \sigma^0 = \sqrt{h/2\mu_0}; \quad \hat{a}^+\hat{a} = n, \quad (8)$$

and use the harmonic oscillator states $|n>$ as eigenstates with eigenvalues $E_n = n\hbar\omega_0$, ignoring the zero-point energy for convenience. The $\hat{a}^+$, $\hat{a}$ operators satisfying the following properties $[\hat{a}, \hat{a}^+] = \hat{a}\hat{a}^+ - \hat{a}^+\hat{a} = 1$; $\hat{a}^+|n> = \sqrt{n+1}|n+1>$; $\hat{a}|n> = \sqrt{n}|n-1>$. The cumulants are calculated by the average value $<y^n> = \frac{1}{Z} \text{Tr}(\rho y^m)$, $m = 1, 2, 3, ..., \rho = \exp(-\beta H), \beta = (k_B T)^{-1}$, where $Z$ is the canonical partition function, $\rho$ with $\beta$ is the statistical density matrix, $k_B$ is Boltzmann’s constant. The corresponding unperturbed quantities are $Z_0 = \text{Tr}(\rho_0)$, and $\rho_0 = \exp(-\beta H_0)$. To leading order in perturbation $\delta U_E$, $\rho = \rho_0 + \delta \rho$ with $\delta \rho$ is given by:

$$\delta \rho = -H_0\rho_0\delta \beta; \quad \delta \rho_0 = -H_0\rho_0\delta \beta \quad (9)$$

we obtained:

$$\delta \rho = \int_0^\beta e^{-\beta H_0}\delta U_E(\beta')d\beta'; \quad \delta \tilde{U}_E(\beta) = e^{\beta H_0}\delta U_Ee^{-\beta H_0}.$$  

If we put unperturbed quantities equal to zero, we have:

$$Z_0 = \text{Tr} \rho_0 = \sum_a \exp(-n\beta\hbar\omega_0) = \sum_0^\infty z^n = \frac{1}{1-z},$$

where $z = e^{-\beta\hbar\omega_0} = e^{-\beta k_B T}$ is the temperature variable and determined by the $\theta_E = \hbar\omega_0 / k_B$ is Einstein temperature. Now we are using above expressions to calculate analytics of the cumulants.

+ The cumulants even order:
\[ \langle y^m \rangle_{\text{even}} \approx \frac{1}{Z} \text{Tr} \rho y^m \approx \frac{1}{Z_0} \text{Tr} \rho_0 y^m = \frac{1}{Z_0} \sum_n e^{-\beta \rho_0 E_n} \langle n | y^m | n \rangle \]

With \( m = 2 \) we have calculation expression of the second cumulant

\[ \langle y^2 \rangle = \sigma^{(2)} = \frac{1}{Z_0} \sum_n e^{-\beta \rho_0 E_n} \langle n | y^2 | n \rangle. \] \hspace{1cm} (10)

Using matrix \( \langle n | y^2 | n \rangle = \langle n | \hat{a} \hat{a} + \hat{a}^\dagger \hat{a}^\dagger | n \rangle = (\sigma_0)^2 (2n + 1) \) and substituting into (10) and applying the mathematical transformations and according to (7) we have expression of second cumulant which is rewritten through \( c_i \) structural parameter:

\[ \sigma^{(2)} = \langle y^2 \rangle = \frac{\hbar \omega_E}{2c_i \Delta \alpha} \frac{(1+z)}{(1-z)}. \] \hspace{1cm} (11)

+ The cumulants odd order:

\[ \langle y^m \rangle_{\text{odd}} \approx \frac{1}{Z} \text{Tr} \rho y^m \approx \frac{1}{Z_0} \text{Tr} \delta \rho y^m \] \hspace{1cm} (12)

With \( m = 1, 3 \) we have expression to calculate first cumulant and third cumulant.

Transformation following matrix correlate with \( \langle y \rangle \) and \( \langle y^3 \rangle \), we have:

\[ \langle n | y^{n+1} \rangle = \sigma_0 \langle n | \hat{a} + \hat{a}^\dagger | n + 1 \rangle = \sigma_0 \sqrt{n + 1} \langle n | n \rangle = \sigma_0 (n + 1)^{1/2}, \] \hspace{1cm} (13)

\[ \langle n | y^n | n + 1 \rangle = (\sigma_0)^3 \left(3n \sqrt{n + 1} + 3 \sqrt{n + 1} \right) \langle n | n \rangle = 3(\sigma_0)^3 (n + 1)^{3/2}, \] \hspace{1cm} (14)

- The first cumulant \( (m=1) \)

\[ \sigma^{(1)} = \langle y \rangle = \frac{1}{Z_0} \sum_{nn'} e^{-\beta \rho_0 E_n} - e^{-\beta \rho_0 E_{n'}} \langle n | D \left( \alpha^2 c_i a - \alpha^3 c_i y^3 \right) | n' \rangle \langle n' | y | n \rangle \]

with \( n' = n + 1 \) and from Eqs. (12, 13) and transform, we have:

\[ \langle y \rangle = \frac{\Delta \alpha^2}{\hbar \omega_E} (\sigma_0)^3 \left[ c_i a - 3c_i \alpha(\sigma_0)^2 \frac{(1+z)}{(1-z)} \right] = \frac{\Delta \alpha^2}{\hbar \omega_E} \frac{2E_{\text{eff}}}{2E_{\text{eff}}} \left[ c_i a - 3c_i \alpha(\sigma_0)^2 \frac{(1+z)}{(1-z)} \right], \]

because \( \langle y \rangle = 0 \) and approximate \( k_{\text{eff}} \approx c_i \Delta \alpha^2 \), the transformation and reduction we obtained first cumulant

\[ \sigma^{(1)} = a = \frac{15\hbar \omega_E}{8c_i \Delta \alpha} \frac{(1+z)}{(1-z)} = \frac{15 \alpha}{4c_i} \times \sigma^{(2)} \] \hspace{1cm} (16)

- The third cumulant \( (m=3) \)

\[ \sigma^{(3)} = \langle y^3 \rangle = \frac{1}{Z_0} \sum_{nn'} e^{-\beta \rho_0 E_n} e^{-\beta \rho_0 E_{n'}} \langle n | \delta U_U | n' \rangle \langle n' | y^3 | n \rangle. \]

From Eqs. (7, 17), we have:

\[ \langle y^3 \rangle = \frac{\Delta \alpha^2}{Z_0} \sum_{nn'} \left[ e^{-\beta \rho_0 E_n} - e^{-\beta \rho_0 E_{n'}} \right] \langle n | c_i a | n' \rangle - \langle n | \alpha c_i y^3 | n' \rangle \langle n' | y^3 | n \rangle \] \hspace{1cm} (18)

Using Eqs. (14, 15), the calculation of Eq.(18) with \( n' = n + 1, \ n' = n + 3, \) respectively, and note that matrix only affect with \( y^3 \) and according to Eqs. (7, 8), we determine third cumulant:

\[ \sigma^{(3)} = \frac{15(\hbar \omega_E)^2}{8c_i \Delta \alpha^2} \frac{(1+10z+z^2)}{(1-z)^2} = \frac{15\hbar \omega_E}{4c_i \Delta \alpha} \frac{(1+10z+z^2)}{(1-z)^2} \times \sigma^{(2)} \] \hspace{1cm} (19)
The results of the numerical calculations according to present method for cumulants good agreement with experimental values for Cu crystal (Table 3). The Figures 1 illustrates good agreement of the second and third cumulants in present theory with experiment values.

Table 3. The comparision of the results of $\sigma^2$ and $\sigma^3$ calculated by present theory with experimental data for Cu crystal at different temperatures.

DISCUSSION AND CONCLUSIONS

Developing further the anharmonic correlated Einstein model we obtained a general theory for calculation cumulants and thermodynamic parameters in XAFS theory including anharmonic contributions. The expressions are described through new structural parameters agree with structural contributions of cubic crystals like face center cubic (fcc), body center cubic (bcc), and results published before [8]. The expression in this work is general case of present procedure when we insert the magnitudes of $c_1, c_2$, from Table 2 into the calculation of the thermodynamic parameters and above obtained expressions of cumulants. The results of the numerical calculations according to present method for cumulants good agreement with experimental values for Cu crystal (Table 3), note that the experimental values from XAFS spectra measured at HASYLAB (DESY, Germany).

With the discovery of the XAFS spectra, it provides the number of atoms and the radius of each shell, the XAFS spectroscopy becomes a powerful structural analysis technique, but the problem remained to be solved is the distribution of these atoms. The factors $c_1, c_2$, introduced in the presented work contains the angle between the bond connecting absorber with each atom and the bond between absorber and backscatterer, that is why they can describe the nearest atoms distributions surround absorber and backscatterer atoms. Knowing structure of the crystals and the magnitudes of $c_1, c_2$, from Table 2 we can calculate the cumulants and then XAFS spectra. But for structure unknown substances we can extract the atomic number from the measured XAFS spectra, as well as, extract the factors $c_1, c_2$, according to our theory from the measured cumulants like Debye-Waller factor to get information about atomic distribution or structure.

The thermodynamic parameters expressions described by second cumulant or Debye-Waller factor is very convenient, when second cumulant $\sigma^{(2)}$ is determined, it allows to predict the other cumulants according to Eqs. (21), (24), consequently reducing the numerical calculations and experimental measurements.
